

Hello, I want to request a proposal for developing a responsive web platform for Ecuador focused on discovering restaurants and local services, with a modern, simple, visually attractive, and scalable experience. The project should work as a marketplace/directory where users can search for restaurants and services by keyword, category, type of food, type of service, zone, and map location, switch between list view and map view, see complete business profiles, save favorites, and leave reviews. The platform must include different roles: client/user, restaurant, service provider, and administrator. A client should be able to register, log in, search, review, save favorites, and manage their profile. Restaurants and service providers should be able to register, subscribe to a plan, and manage one or more businesses from the same account. The administrator must also be able to create and edit businesses manually, without depending on the client to upload the information themselves.

The platform must include a strong home page with a header, hero section, search bar, selector for Restaurants / Services, featured areas, new businesses, promotional sections, community/social sections, blog/guides, and footer. The search/listing area must support advanced filters and a clean, attractive display of results. Each restaurant and service must have its own public profile page. A restaurant profile should include overview, menus, products/dishes, photos, reviews, about section, environment, location, branches, and videos. A service profile should include overview, services offered, portfolio, reviews, about section, location, and contact details. There must also be a client profile where the user can see their personal info, reviews made, and saved businesses.

The business side must include a restaurant dashboard and a service-provider dashboard, where owners can manage their information, photos, products, menus, reviews, and see analytics depending on the plan and permissions enabled. There must also be a personal account settings page for the owner of the account, separate from the restaurant/service business data, including personal info such as name, surname, ID/RUC, date of birth, contact details, and verification status. Some fields should become locked after verification, with an option to request a special verification update. There must also be a "My Businesses" section where the account owner can see active restaurants and active services, add a new restaurant, add a new service, edit, open the panel, open the public profile, deactivate, and manage each business from one place.

The system must support subscription plans such as Silver, Gold, and Diamond, with monthly or annual options. Not all plans should have the same permissions. For example, a basic plan may only allow the business to appear listed without being able to fully manage its information, while higher plans should allow the owner to edit their profile, upload photos, add dishes, upload menus, respond to reviews, manage branches, and access analytics. The admin must have a complete subscription management module to see active businesses, inactive businesses, expiring subscriptions, expired accounts, free accounts, current plan, renewal dates, and upgrade/downgrade options. I also need an admin analytics panel to track which businesses receive the most profile visits, the most WhatsApp button clicks, the most reviews, and which restaurants or services are performing best overall. Likewise, the owner of the business should only see analytics if that privilege is enabled in their plan or permissions.

The platform should be responsive for desktop and mobile web, simple to use, but designed in a way that it can scale in the future into a larger business model with orders, reservations, and delivery. My intended rollout is: Phase 1 should focus on the responsive website, search, map, listings, business profiles, user accounts, dashboards, subscriptions, and administration. Phase 2 can include orders, cart, reservations, and online payments. Phase 3 can include delivery, riders, and order tracking. I do not yet have a payment gateway selected, but I would like the project to be prepared for a future integration, possibly with PayPhone. Since the platform is for Ecuador, I would also like to know if Google Maps is the best option for the map/search component.

Regarding reviews, I would like a system that reduces fake or harmful reviews. Ideally, reviews should be tied to a logged-in account and, if possible, have some form of verification or moderation. If there is no legal or technical way to directly use external review systems, then I would prefer that reviews pass through some form of internal verification or admin moderation. I do not yet have professional UI/UX designs; I only have some non-professional reference mockups to explain the idea, so I would like the design to be clean, modern, functional, and not overly complicated, and if you already have suitable templates or a base design approach for this kind of platform, that would be even better. Please include in your offer the recommended stack, hosting proposal, scalability considerations, estimated delivery by phases, and confirmation that the final delivery includes the working project, source code, and documentation.

I want to build a responsive web platform for Ecuador focused on discovering restaurants and local services. The idea is a marketplace/directory where users can search businesses by keyword, food type, category, service type, tags, zone, or map location. The platform should allow users to explore results in list view or map view, see full business profiles, save favorites, and leave reviews. Each business profile should include information such as description, photos, menus, products or dishes, location, branches, contact information, and reviews. Restaurants should also be able to upload dishes (around 50 items), photos, and up to two menu files, while service providers should be able to upload a portfolio of their work. The system must support tags and categories (for example cuisine types, food styles like vegan or healthy, and business types such as restaurant, dark kitchen, catering, etc.).

The platform must support four roles: client, restaurant owner, service provider, and administrator. Clients can register, log in, search businesses, leave reviews, and save favorites. Restaurant owners and service providers can create accounts and manage one or multiple businesses depending on their subscription plan. They should have a private dashboard where they can manage their profile, menus, products, photos, reviews, and settings. The owner account should also have a personal profile configuration (name, ID/RUC, email, phone, location, etc.) separate from the business information. The system should include a "My Businesses" section where an owner can see all their restaurants or services, add new ones, edit them, access their dashboard, or deactivate them.

The platform will include subscription plans (for example Silver, Gold, and Diamond) that can be

monthly or yearly. Each plan should unlock different privileges. Basic plans may only allow the business to appear listed without full editing control, while higher plans allow the owner to fully manage their information, upload photos, add dishes or services, respond to reviews, and view statistics. The administrator must have a complete admin panel to manage users, restaurants, services, reviews, categories, tags, zones, and subscriptions. The admin should also be able to create or edit businesses manually if needed. There must be a subscription management system to track active plans, expiring plans, expired accounts, free listings, and upgrades or downgrades.

The system should include analytics and statistics, such as profile visits, clicks on the WhatsApp contact button, menu views, reviews, and general performance metrics. Admin should be able to see global analytics, while business owners can only see their statistics if the plan or permissions allow it. Reviews should ideally require users to be logged in and should have moderation or verification to avoid fake or harmful reviews. The project should initially be web-only but fully responsive for mobile and desktop, and designed in a simple, modern interface. I do not yet have professional UI/UX designs, only rough mockups to explain the idea, so I am open to using clean templates or design suggestions.

The project should also be built with scalability in mind. Phase 1 will include the website, search system, map integration (preferably Google Maps), business profiles, dashboards, subscriptions, and admin management. Phase 2 may include orders, reservations, and online payments. Phase 3 may include delivery and rider management. I do not yet have a payment gateway but would like the system prepared for future integration, possibly with PayPhone. The final delivery should include the working platform, source code, and documentation explaining how the system works and how to manage it.
